

# CSC380: Principles of Data Science

Data Analysis, Collection, and Visualization 1

Xinchen Yu

### **Announcements**

No in-person lecture on Feb 8 (Thurs) and Feb 13 (Tues).

Recordings of Data Summarization will be uploaded to D2L.

HW4 out this Thursday, due next Friday.

- Data Collection and Sampling
- Data Visualization
- Data Summarization

### **Motivation**

Not understanding how data are collected is one of the top reasons behind bad data science...

...we will not do data collection or experimental design, but should be familiar with the basics

## Statistical Analysis

- 1. Plan research design
- 2. Collect data (essentially, sampling)
- Will focus on these
- 3. Visualize and summarize the data (plots and summary stats)
- 4. Make inferences from data (i.e., estimate stuff, test hypotheses, ...)
- 5. Interpret results

### Research Design

**Randomized Control.** Researcher controls treatment among groups. Used to assess *causal* relationships. Stronger than correlational study but difficult to conduct. (e.g., clinical trials)

**Observational.** Collect data by "observing" passively. If there are treatments (i.e., vaccines), they are not under control of the researcher.

- Natural Experiment. Observe naturally-occurring phenomena. Approximates a controlled study, despite the researcher not having control of any groups. (e.g. Helena, Montana banned smoking ban in all public spaces for six months –before/after this ban)
- Case Studies and Surveys. Analysis based on previously-collected data. (e.g., Analysis of US census data, or US current population survey (CPS))

### Recall: Explanatory, response variable

Example: Say we study the relationship between Smoking vs Cancer

Independent variable: variables that are manipulated or are changed by researchers and whose effects are measured and compared.

= explanatory variable

Dependent variable: the variable that depends on independent variable (or speculated to do so).

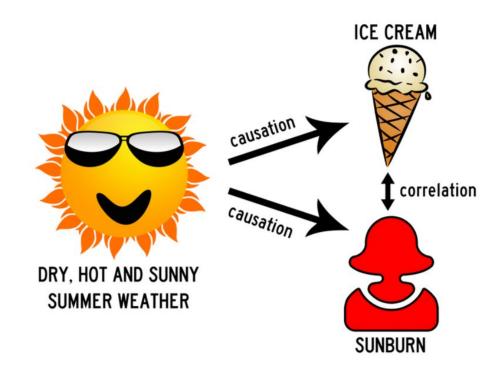

= response variable

# Recall: Explanatory, response variable

Research question	Independent variable	Dependent variable(s)
Do tomatoes grow fastest under fluorescent, incandescent, or natural light?	Type of light the tomato plant is grown under	The rate of growth of the tomato plant
What is the effect of intermittent fasting on blood sugar levels?	<ul> <li>Presence or absence of intermittent fasting</li> </ul>	Blood sugar levels
Is medical marijuana effective for pain reduction in people with chronic pain?	Presence or absence of medical marijuana use	<ul><li>Frequency of pain</li><li>Intensity of pain</li></ul>
To what extent does remote working increase job satisfaction?	<ul> <li>Type of work environment (remote or in office)</li> </ul>	<ul> <li>Job satisfaction self- reports</li> </ul>

### Causation vs. Correlation

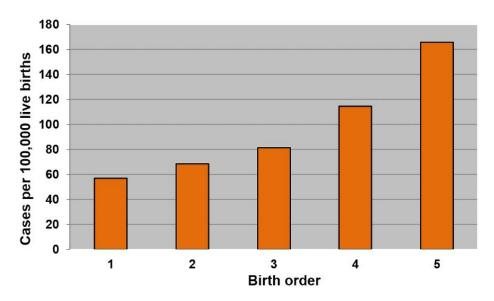

Studies generally try to show *either* correlation (association) or causation, but they are not the same...

# Confounding Variables

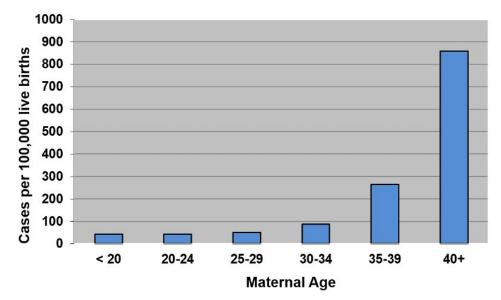

A variable that influences the *response* but is unaccounted for in data collection

**Example:** You are studying whether **birth order** affects **Down's Syndrome** in the child. You collect samples of children, their birth order, and cases of Down's syndrome.

# Confounding Variables

You went on to collecting the maternal age data.

So.. both maternal age and birth order is associated with Down's syndrome?

# Confounding Variables

A variable that influences the *response* but is unaccounted for in data collection

**Example:** You are studying whether **birth order** affects **Down's Syndrome** in the child. You collect samples of children, their birth order, and cases of Down's syndrome.

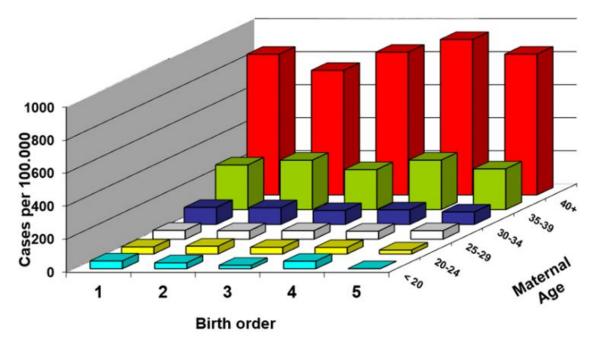

**Explanation:** Maternal age (confounder) was not recorded. Two scenarios:

- 1. Higher maternal age is directly associated with Down's syndrome, regardless of birth order.
- Maternal age directly assoc. with birth order (mother is older with later children), but not directly associated with Down's syndrome.

### Controlling for Confounders

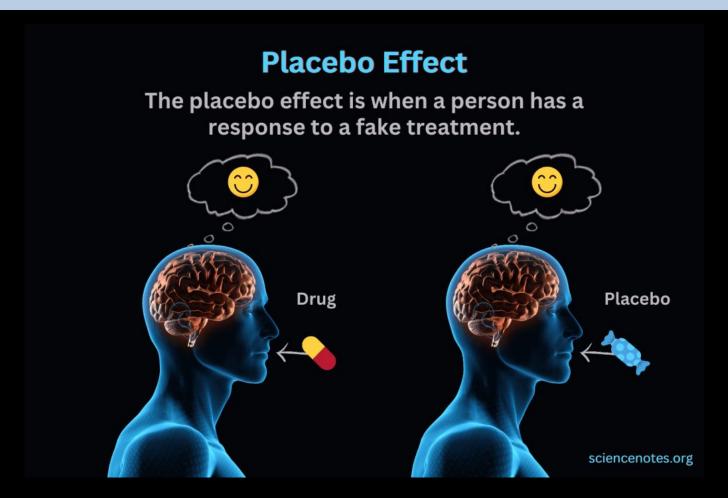

<u>Stratified Sampling</u>: Divide population into smaller groups. Previous example can divide population of children by maternal age at birth and collect data from each stratum

### **Approach**

- 1. Control confounders: design treatments
- 2. Randomize the assignment of subjects to treatments (to eliminate bias due to systematic differences in categories)
- 3. Replicate experiment on many subjects, to obtain statistically meaningful results

### Placebo Effect

### Example: Pfizer COVID Phase 3 Vaccine Trials

- the tendency of any medication or treatment, even an inert or ineffective one, to exhibit results simply because the recipient believes that it will work.
- 1. Placebo Control: Subjects are randomly selected to receive either the vaccine or an injection of saline solution

**2. Randomize:** Stratified sampling with age strata: 12-15yrs, 16-55yrs, 55+yrs

3. Replicate: Experiment is repeated at multiple sites in several countries

### Example: Pfizer COVID Phase 3 Vaccine Trials

The landmark phase 3 clinical trial enrolled 46,331 participants at 153 clinical trial sites around the world.

### Trial Geography

Our trial sites are located in Argentina, Brazil, Germany, Turkey, South Africa and the United States.

#### Participant Diversity

Approximately 42% of overall and 30% of U.S. participants have diverse backgrounds.

Participants	Overall Study	U.S. Only
Asian	5%	6%
Black	10%	10%
Hispanic/Latinx	26%	13%
Native American	1.0%	1.3%

49.1% of participants are male and 50.9% are female

#### Participant Age

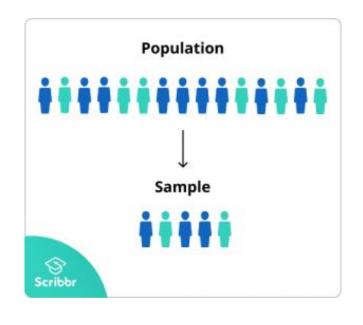

Ages 12-15	2,260
Ages 16-17	754
Ages 18-55	25,427
Ages 56+	17,879

### Data Collection

### Population vs. Sample

Generally infeasible to collect data from entire population

**Population** Entire group that we want to draw conclusions about.

Can be defined in terms of location, age, income, etc.

**Sample** Specific group that we collect data from.

## Reasons for Sampling

**Necessity** It is usually impractical or impossible to collect data from an entire population due to size or inaccessibility.

**Cost-effectiveness** There are fewer participant, laboratory, equipment, and researcher costs involved.

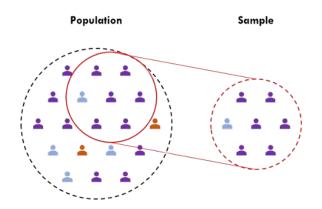

**Manageability** Storing data and running statistical analyses is easier on smaller datasets.

## Population Parameter vs. Sample Statistic

**Population parameter** A measure that describes the whole population.

<u>Sample statistic</u> A measure that describes the sample and reflects the population parameter.

**Example** We are studying student **political attitudes** and ask students to rate themselves on a scale: 1, very liberal, to 7, very conservative. The **population parameter** of interest is the average political leaning. The sample mean, say 3.2, is our **statistic**.

# Sampling Error

The sampling error is the difference between the population parameter and the sample statistic.

- Sampling errors are normal, but we want them to be low
- •Samples are **random**, so sample statistics are estimates and thus subject to random noise
- •Sample bias occurs when the sample is not representative of the population (for various reasons)

# Sampling Methods

Sampling must be conducted properly, to avoid sample bias

Two primary types of sampling...

**Probability Sampling** Random selection allowing strong statistical inferences about the population

Non-Probability Sampling Based on convenience or other criteria to easily collect data (but no random sampling)

# Simple Random Sample (SRS)

Each member of the population has the *same chance* of being selected (i.e., uniform over the population)

# Example : American Community Survey (ACS)

Each year the US Census Bureau use simple random sampling to select individuals in the US. They follow those individuals for 1 year to draw conclusions about the US population as a whole.

# Simple Random Sample (SRS)

Each member of the population has the *same chance* of being selected (i.e., uniform over the population)

- Most straightforward probability sampling method
- Impractical unless you have a complete list of every member of population

### **Systematic Sample**

Select members of population at a regular interval, determined in advance

**Example** You own a grocery store and want to study customer satisfaction. You ask *every 20<sup>th</sup>* customer at checkout about their level of satisfaction.

**Note** We cannot itemize the whole population in this example, so SRS is not possible.

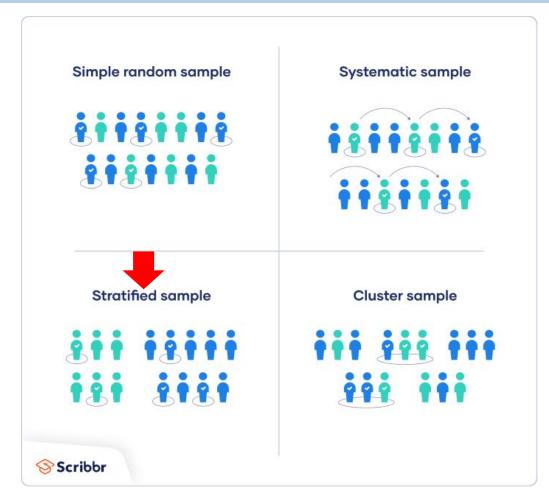

### **Systematic Sample**

Select members of population at a regular interval, determined in advance

- Imitates SRS but is easier in practice
- Do not use when there can be a pattern. E.g., survey at the exit of a rollercoaster with N seats but with every N-th customer.

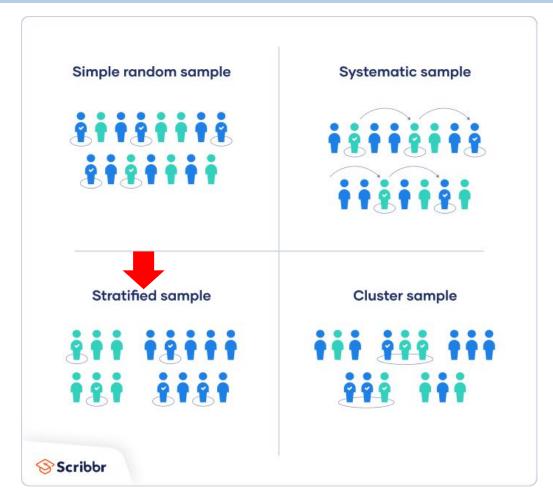

Alternative: use a Bernoulli(p) (e.g., p=1/20)

### **Stratified Sample**

Divide population into homogeneous subpopulations (strata). Probability sample the strata.

**Example** We wish to solicit opinions of UA CS freshman by asking 100 of them, but they are about 14% women. SRS could easily fail to capture adequate number of women. We divide into men / women and perform SRS within each group.

### **Stratified Sample**

Divide population into homogeneous subpopulations (strata). Probability sample the strata.

- Use when population is diverse and want to accurately capture characteristic of each group
- Ensures similar variance across subgroups
- Lowers overall variance in the population

### **Cluster Sample**

Divide population into subgroups (clusters). Randomly select entire clusters.

**Example** We wish to study the average reading level of *all* 7<sup>th</sup> graders in the city (population). Create a list of all schools (clusters) then randomly select a subset of schools and test every student.

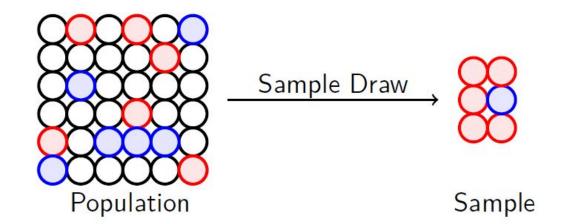

### **Cluster Sample**

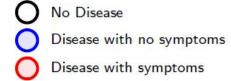

Divide population into subgroups (clusters). Randomly select entire clusters.

- This is single-stage cluster sampling
- Multi-stage avoids sampling every member of a group
- Related to stratified sampling, but groups are not homogeneous

### Sampling Bias

Occurs if data are collected in a way that some members of the population have lower/higher probability of being sampled than others

## Sampling Bias

Sometimes is unavoidable (e.g., not all members are equally accessible) but (1) you should be aware of it

(2) must be corrected if possible at all

**Example** We conduct a poll by randomly calling numbers in a phone book. People that have less time are less likely to response. Called **non-response bias**.

## Common Types of Sampling Bias

**Self-selection:** Possible whenever members under study have control over whether to participate.

• E.g., online or phone-in poll—user can choose whether to initiate participation.

Exclusion: Excluding certain groups from the sample.

• E.g., longitudinal data collection for 2 years in a town where we exclude groups that move in or out.

Survivorship: Only surviving subjects are selected.

• E.g., studying improvements on the retention rate of CS majors by surveying CS graduates.

# Example of Bias in a Simple Random Sample

SRS is least prone to bias, but not always...

You want to study procrastination and social anxiety levels in undergraduate students at your university using a simple random sample. You assign a number to every student in the research participant database from 1 to 1500 and use a random number generator to select 120 numbers.

What is the cause of bias in this simple random sample?

# Example of Bias in a Simple Random Sample

### SRS is least prone to bias, but not always...

You want to study procrastination and social anxiety levels in undergraduate students at your university using a simple random sample. You assign a number to every student in the research participant database from 1 to 1500 and use a random number generator to select 120 numbers.

Although you used a random sample, not every member of your target population –undergraduate students at your university – had a chance of being selected. Your sample misses anyone who did not sign up to be contacted about participating in research. This may bias your sample towards people who have less social anxiety and are more willing to participate in research.
